Recurrent Neural Networks (RNNs)

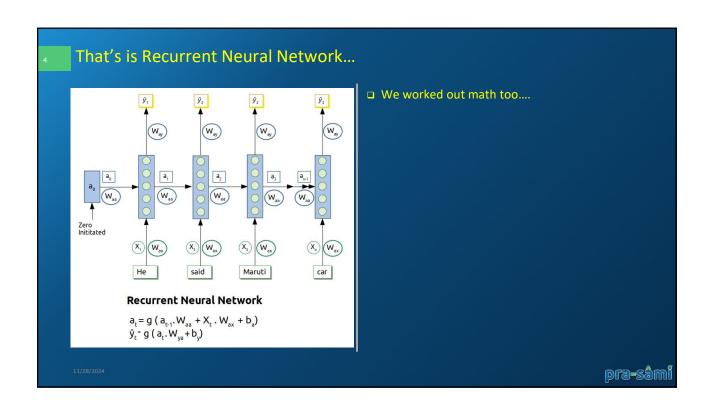

Recurrent Neural Networks take the previous output or hidden states as inputs

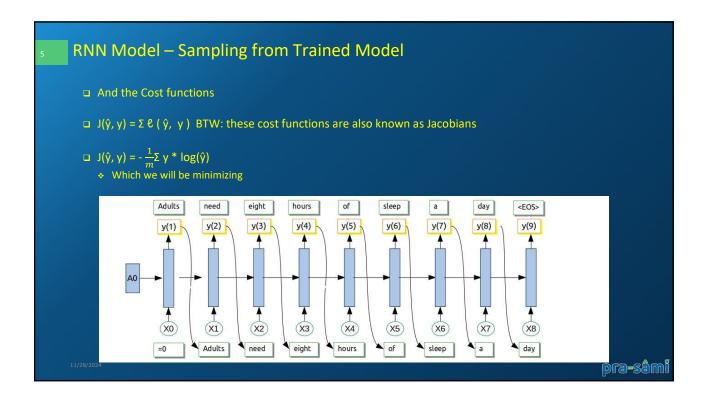

The composite input at time "t" has some historical information about the happenings at time T < "t".

RNNs are useful as their intermediate values (state) can store information about past inputs for a time that is not fixed a priori

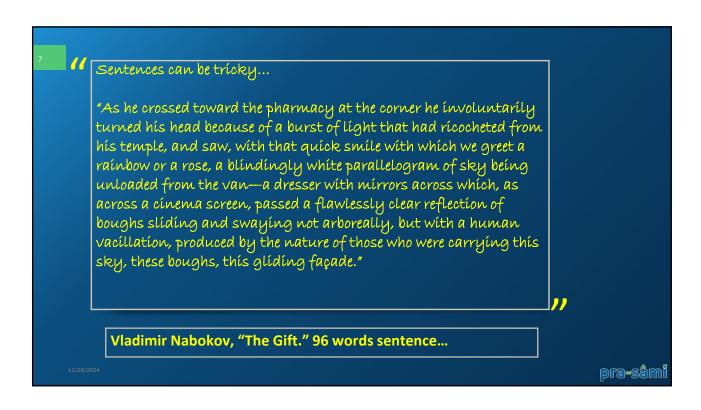

Note that the weights are shared over time

Essentially, copies of the RNN cell are made over time (unrolling/ unfolding), with different inputs at different time steps

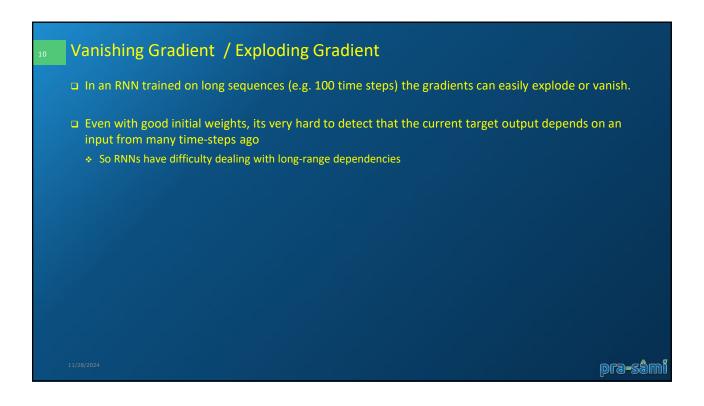

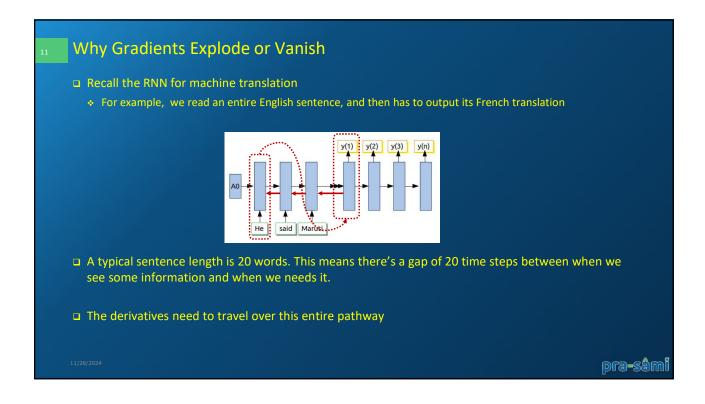

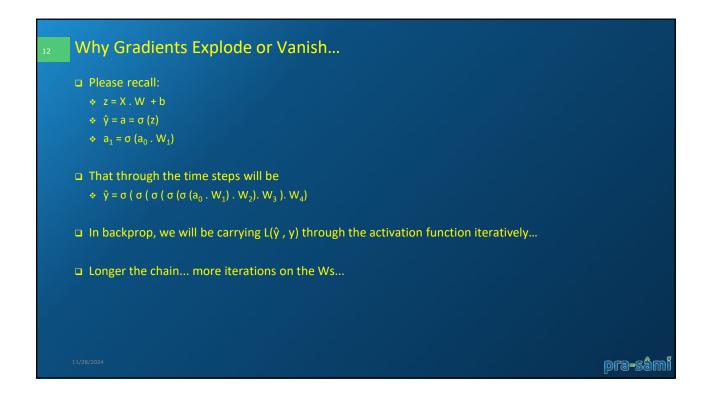

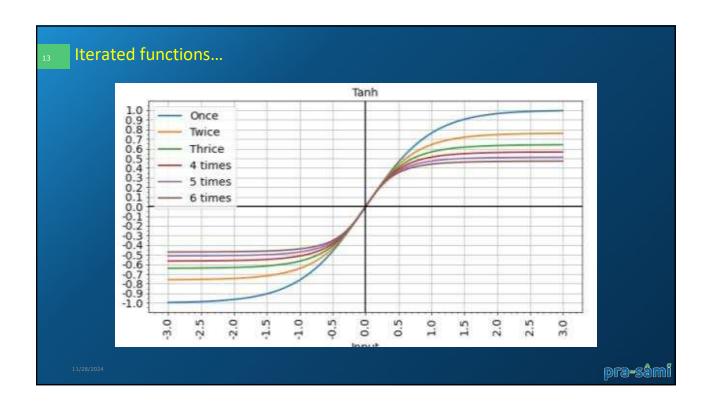

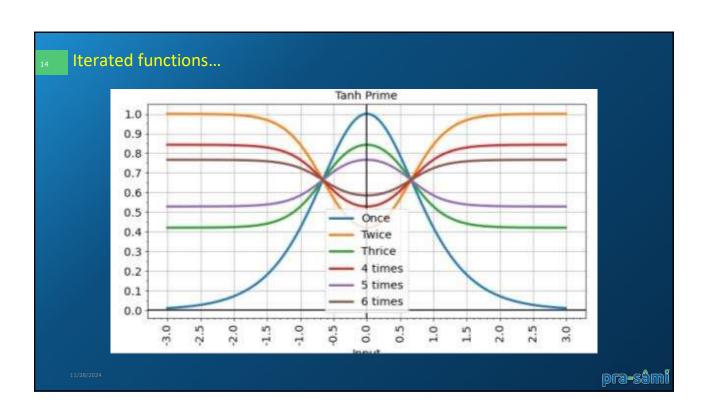

What happens to the magnitude of the gradients as we back propagate through many layers? If the weights are small, the gradients shrink exponentially If the weights are big the gradients grow exponentially Typical feed-forward neural nets can cope with these exponential effects because they only have a few hidden layers We can manage gradients by initializing the weights very carefully in feed-forward networks We have already experienced by using appropriate Is it applicable to RNNs as well? ■ Is it applicable to RNNs as well?

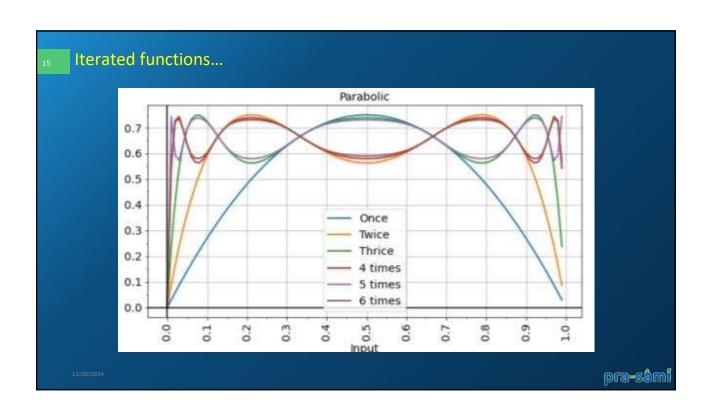

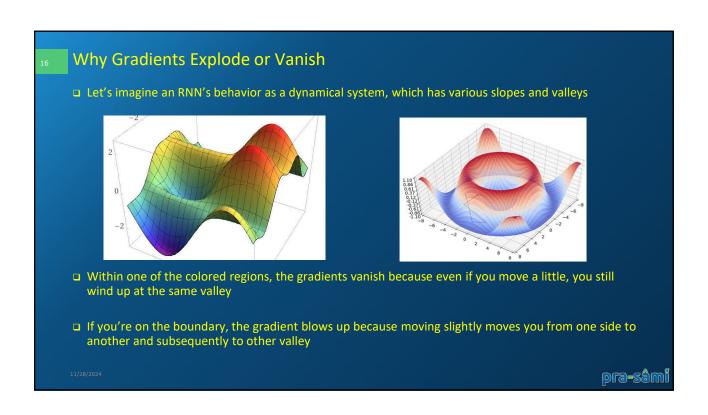

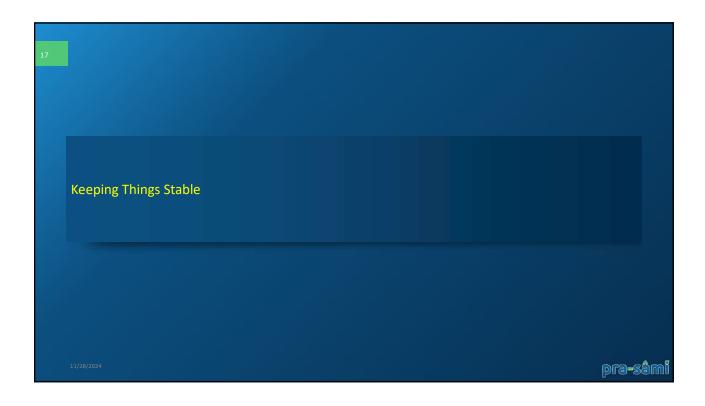

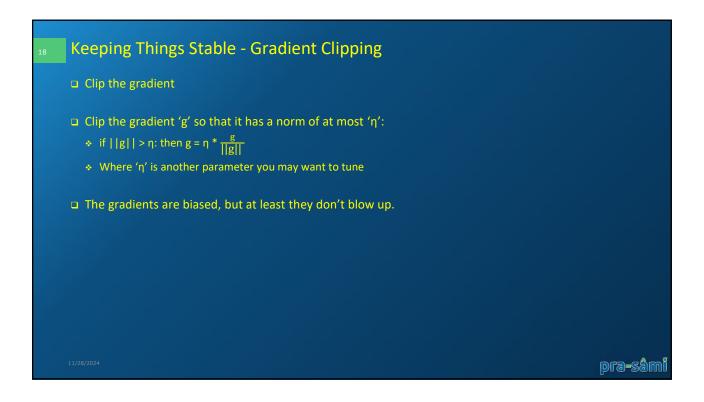

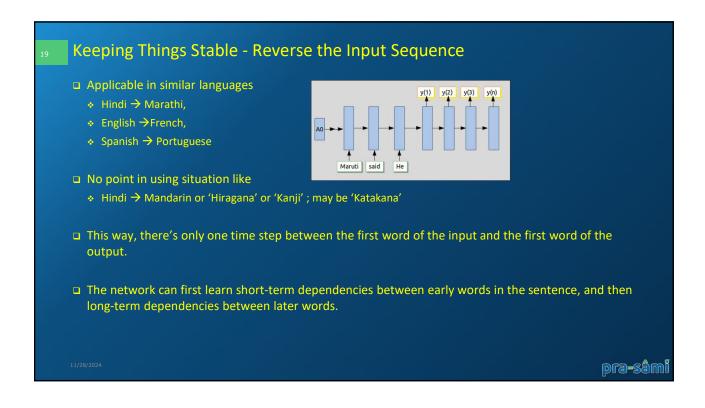

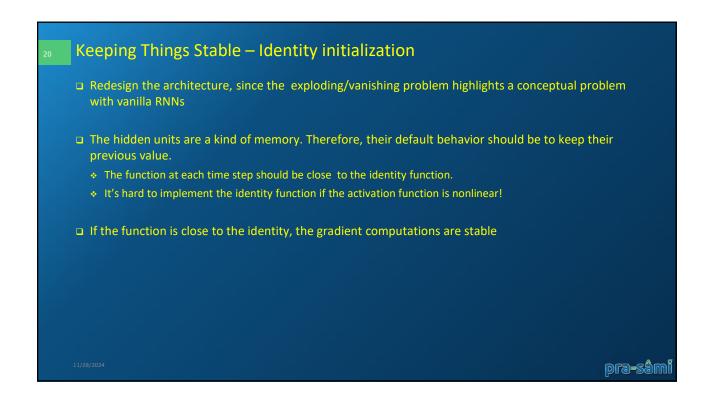

Keeping Things Stable — Identity initialization The identity RNN architecture: [Le et al., 2015. A simple way to initialize recurrent networks of rectified linear units.] The activation functions are all ReLU, Recurrent weights are initialized to the identity matrix Proof: This simple initialization trick achieved some neat results; For instance, it was able to classify MNIST digits which were fed to the network one pixel at a time, as a length-784 sequence
